4. Access Control

Computer Security Courses @ POLIMI

What is Access Control?

- A binary decision:
  - Access either *allowed* or *denied*
  - What could *possibly* go wrong?
- Scale goes wrong!
  - You cannot explicitly *list* the answers
  - Need to condense them in *rules*
- Questions
  - How do we *design* the access rules?
  - How do we *express* the access rules in practice?
  - How do we appropriately *apply* them?

Who Does it? The Reference Monitor

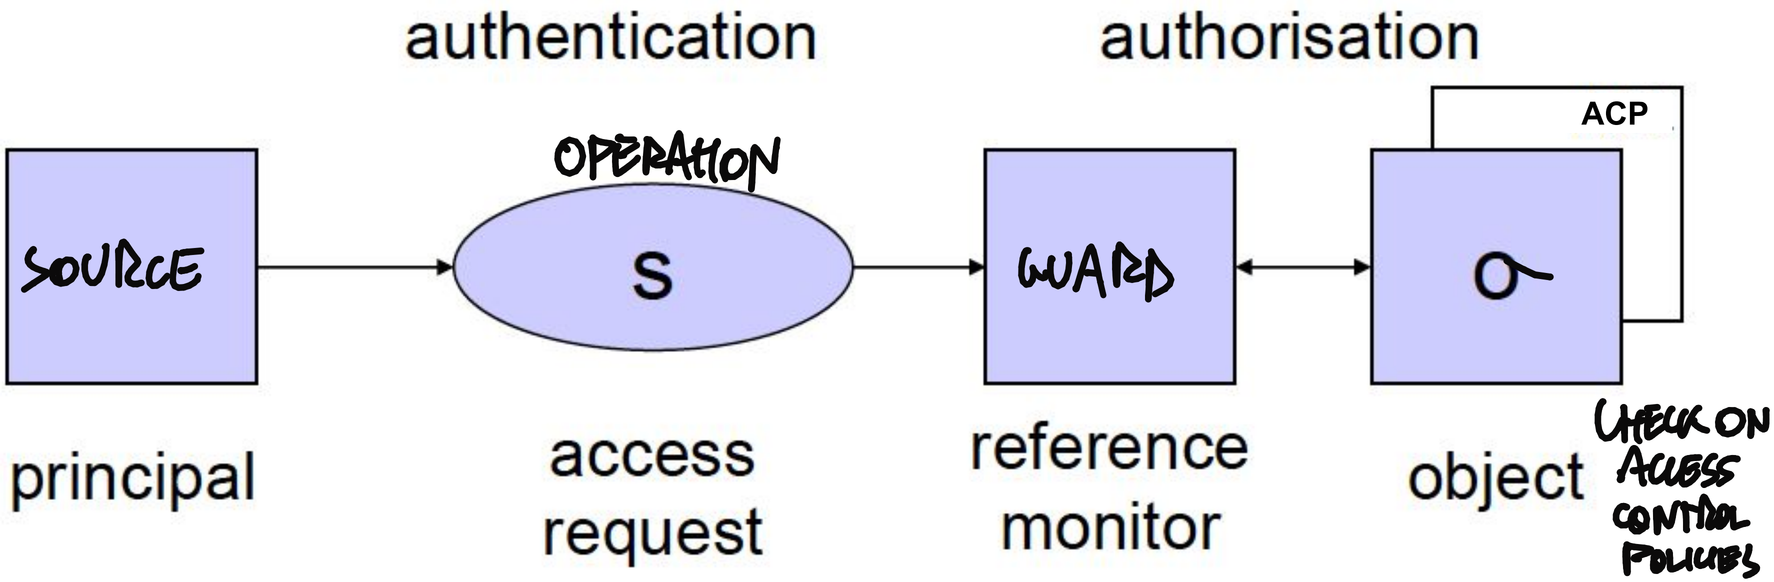
Enforces access control policies ("who does what on which resource"). All modern kernels have a reference monitor implementation.

Requirements for the RM:

- Tamper proof
- Cannot be bypassed
- Small enough to be verified/tested

J. Anderson, 1972 "Computer Security Technology Planning Study"

Authentication & Authorization



Authentication & Authorization

- **Authentication**: reference monitor verifies the identity of the principal (user) making the request:
  - User enters username and password.
  - If the values entered are correct, the user is "authenticated".
    - We could say: "The machine now runs on behalf of the user".
  - This might be intuitive, but it is imprecise.
    - Log on creates a **process** that runs with access rights assigned to the user.
    - Typically, the process runs under the user identity of the user who has logged on.

Authentication & Authorization

- **Authentication**: reference monitor verifies the identity of the principal (user) making the request.
- **Authorization**: reference monitor decides whether access is granted or denied.
  - <u>Reference monitor has to find and evaluate the security policy relevant for the given request.</u>

"Easy" in centralized systems but in distributed systems,

- how to find all relevant policies?
- how to make decisions if policies may be missing?

Users & User Identities

- Requests to reference monitor do not come directly from a user or a user identity, but from a **process**.
- The active entity making a request within the system is called the **subject**.
- You must distinguish between these concepts:
  - **User**: person;
  - **Principal (User identity)**: name used in the system, possibly

    associated with a user; Active entity.
  - **Subject: Process** running under a given user identity.
  - **Object**: Passive entity – file or resource. IN THE OS
  - **Access operations**: Vary from basic memory access (read, write) to method calls in object-oriented systems. ANY OPERATION TO THE OBJECT

Access control models

Can be roughly divided in

- Discretionary Access Control (DAC)
- Mandatory Access Control (MAC)
- Role-Based Access Control (RBAC)

Difference between DAC and MAC

- who assigns privileges

RBAC abstracts roles from identities

Discretionary Access Control

- Resource owner *discretionarily* decides its access privileges
  - Stefano creates a file
    - Assigns Federico the privilege of reading it
- If this sounds "normal" it is because **all** off-the-shelf OSs implement DAC
  - Windows
  - Linux and other UNIX flavors
  - Mac OS X
  - Also applications, social networks…mostly DAC!

Examples of DAC systems

- UNIX
  - **Subjects**: users, groups
  - **Objects**: files (everything, really)
  - **Actions**: read, write, execute
- Windows (not the 95/98/ME branches)
  - **Subjects:** with *roles* instead of *groups*, multiple ownership of users and roles over files
  - **Objects**: files and “other” resources
  - **Actions**: delete, change permissions, change ownership.

Permissions (r, w, x) **Subjects (user, group)** **Objects (files, dirs, ...)**

General model of DAC systems

- We need to model the following entities:
  - **Subjects** who can exercise privileges (a.k.a., rights)
  - **Objects** on which privileges are exercised
  - **Actions** which can be exercised
- **Protection state**: a triple (S, O, A)
  - A: matrix with S rows and O columns
  - $A[s,o]$: privileges of subject s over object o

	file1	**file2**	**directoryX**
Alice	Read	Read, Write, Own	
Bob	Read, Write, Own	Read	Read, Write, Own
Charlie	Read, Write		Read

Lampson ‘71, Graham and Denning ‘72, **H**arrison, **R**uzzo and **U**llmann ‘76 -> **HRU model**

Transitions in the HRU model

- **Basic operations**
  - create (or destroy) subject $<s>$
  - create (or destroy) object $<o>$
  - add (or remove) $<permission>$ into $[s,o]$ matrix
- **Transitions**: sequences of basic operations
  - *"create file (subject u; file f)"*:
    - create object f
    - add “own” into $[u,f]$
    - add “read” into $[u,f]$
  - Is this right?

Transitions in the HRU model

- **Basic operations**
  - create (or destroy) subject $<s>$
  - create (or destroy) object $<o>$
  - add (or remove) $<permission>$ into $[s,o]$ matrix
- **Transitions**: sequences of basic operations
  - *"create file (subject u; file f)"*:
    - create object f
    - add “own” into $[u,f]$
    - add “read” into $[u,f]$
  - Is this right? No, we need to check if f existed before, otherwise u would be stealing it away!
  - We need an “if” construct for modeling transitions

Safety problems

- From an initial configuration, given a sequence of transitions, can s obtain a right r on f?
  - Obviously, yes if the owner o allows it!
  - But, if the owner does not?
    - If it happens, set of commands **unsafe by design**!
- More formally
  - Given an initial protection state and set of transitions, is there **any sequence of transitions that leaks** a certain right r (for which the owner is removed) into the access matrix?
  - If not, then the system is safe with respect to right r
- In a generic HRU model (with infinite resources): **undecidable** problem
  - Decidable in mono-operational systems, (substantially useless, e.g., you cannot create a file and own it)
  - .. or if subjects/objects are finite.

Common DAC Implementations

- Reproduction of HRU models
- Access matrix is a sparse matrix
- Alternative implementations:
  - **Authorizations table:** records non-null triples S-O-A, typically used in DBMS
  - **Access Control Lists:** records by column (i.e., for each **object**, the list of subjects and authorizations)
  - **Capability Lists:** records by row (i.e., for each **subject**, the list of objects and authorizations)

Access Control vs Capability Lists

Access Control Lists

- Focus on the object
- ACLs ≡ columns of the access control matrix

USERS THAT CAN ACCESS TO THE OBJECT

fun.com	Alice: {exec}	Bill: {exec,read,write}

Capability Lists

- Focus on the subject
- Capabilities ≡ rows of the access control

ACTIONS THAT CAN BE EXECUTED

Alice	edit.exe: {exec}	fun.com: {exec,read}

HOW TO CHOOSE?

ACLs vs Capability Lists

ACLs

- efficient with **per object** operations
- Most common case
- Some systems (e.g., POSIX) use abbreviated ACLs
- Cannot have multiple owners (partially achievable via groups).

Capabilities

- efficient with **per subject** operations
- Usually **objects** change and **subjects** stay, so inefficient
- Capabilities are optional in POSIX (Linux and BSD).

General DAC shortcomings

- Cannot prove safety
- Control access to objects but not to the data inside objects (granularity)
  - Susceptible to *malicious user* problem
  - Susceptible to *trojan horse* problem: malicious program running with privileges of the user
- Problems of <u>scalability and management</u>
  - each user-owner can potentially compromise security of the system with their own decisions

Mandatory Access Control (MAC)

Idea: do not let owners assign privileges.

Privileges are set by a security **administrator**:

- E.g., defines a **classification** of *subjects* (or "clearance") and *objects* (or "sensitivity").

The **classification** is composed of:

- A strictly ordered set of **secrecy levels**.
- A set of **labels**.

(example of MAC rules in SELinux)

SELinux Administration

File Help

Select:
- Status
- Boolean
- File Labeling
- User Mapping
- SELinux User
- Translation
- Network Port
- Policy Module

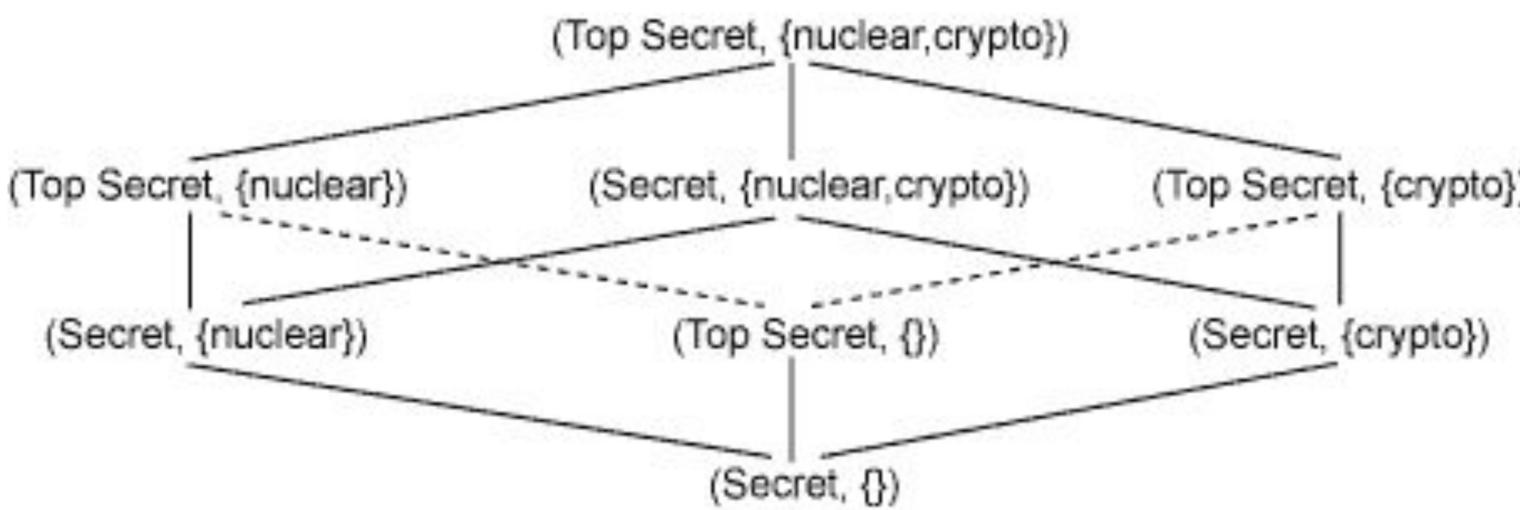
Secrecy Levels + Labels = Lattice (LBAC)

Classification = *partial order relationship*.

Dominance in a lattice is defined as:

$\{C_1,L_1\} \geq \{C_2,L_2\} \Leftrightarrow C_1 \geq C_2$ and $L_2 \subseteq L_1$



(reflexive, transitive, antisymmetric property)

Bell-LaPadula Model (BLP) - 1

Defines two MAC rules:

1. **Rule 1** (no read up, "simple security property")
   A subject s at a given secrecy level **cannot read** an object o at a **higher** secrecy level.
1. **Rule 2** (no write down, "star property")
   A subject s at a given secrecy level **cannot write** an object o at a **lower** secrecy level.

Defines one DAC rule:

Rule 3 (Discretionary Security Property) states the use of an access matrix to specify the discretionary access control.

Bell-LaPadula Model (BLP) - 2

Tranquility property: secrecy levels of objects cannot change dynamically.

Result: monotonic flow of information toward higher secrecy levels

- need of **trusted subjects** who can declassify or sanitize documents

Limitations: does not address integrity. There are other models for integrity, e.g. http://en.wikipedia.org/wiki/Biba_Model

MAC Information Flow

Conclusions

Access control, or authorization, defines *subjects*, *objects*, and *actions* in a system.

Access control **models** define how actions are (un)assigned to subjects and objects.

DAC are more common and “natural” than **MAC**, but can coexist.
